

HTML (HyperText Markup Language)

The backbone of text for the WWW. Computer systems read it to display content.

The Syntax structure uses opening and closing tags enclosed by angle brackets.

E.g., `<p>This is a paragraph with <strong>bold</strong> text.</p>`

Lets you do common functions like

- Layout Pages: Headers, Sidebars, Footers
 - Style: How items look
 - Media: Put in images, videos, audio
 - Collect input: Forms, checkboxes, buttons
 - Connect external files: JavaScript, CSS (Cascading Style Sheets)
 - JavaScript is the programming language that makes web pages interactive. It handles actions like pop-up menus, slideshows, notifications, and form submissions.
 - CSS manages layouts, colors, fonts, spacing, and animations, separating a website's content from its design
- "HTML = Skeleton, CSS = Skin/clothing, = Java = Brian/Muscle"*

Markdown

Designed to let people follow HTML and format text so it's simple to read and easier to code.

Feature	Markdown	HTML
Primary Focus	Human-readable content writing	Browser-rendered web layout
Syntax Style	Simple plain-text symbols (<code>#</code> , <code>**</code> , <code>[-]</code>)	Angle-bracket tags (<code><h1></code> , <code></code> , <code><a></code>)
Flexibility	Highly restricted; no custom fonts, colors, or CSS	Unlimited; supports styling (CSS), scripts (JS), and interactive SVGs
Token Efficiency	Very high (uses ~68% fewer tokens than HTML)	Low (adds significant overhead due to repetitive boilerplate)
Version Control	Clean, highly legible <code>git</code> diffs	Noisy, complex diffs filled with layout changes
